NOTICE TO FLOOD INSURANCE STUDY USERS

Communities participating in the National Flood Insurance Program have established repositories of flood hazard data for floodplain management and flood insurance purposes. This Flood Insurance Study (FIS) report may not contain all data available within the Community Map Repository. Please contact the Community Map Repository for any additional data.

The Federal Emergency Management Agency (FEMA) may revise and republish part or all of this FIS report at any time. In addition, FEMA may revise part of this FIS report by the Letter of Map Revision process, which does not involve republication or redistribution of the FIS report. Therefore, users should consult with community officials and check the Community Map Repository to obtain the most current FIS report components.

Selected Flood Insurance Rate Map panels for this community contain information that was previously shown separately on the corresponding Flood Boundary and Floodway Map panels (e.g., floodways, cross sections). In addition, former flood hazard zone designations have been changed as follows:

Old Zone:

A1 through A30
B
C

New Zone:

AE
X (Shaded)
X

Initial Countywide FIS Effective Date: TBD

FLOOD INSURANCE STUDY

NOBLE COUNTY, INDIANA AND INCORPORATED AREAS

1.0 INTRODUCTION

1.1 Purpose of Study

This Flood Insurance Study (FIS) revises and supersedes the FIS reports and Flood Insurance Rate Maps (FIRMs) in the geographic area of Noble County, Indiana, including the Cities of Kendallville and Ligonier, the Towns of Albion, Avilla, Cromwell, Rome City, and Wolcottville, and the unincorporated areas of Noble County (hereinafter referred to collectively as Noble County), and aids in the administration of the National Flood Insurance Act of 1968 and the Flood Disaster Protection Act of 1973. This study has developed flood risk data for various areas of the community that will be used to establish actuarial flood insurance rates and to assist the community in its efforts to promote sound floodplain management. This information will also be used by Noble County to update existing floodplain regulations as part of the Regular Phase of the National Flood Insurance Program (NFIP), and by local and regional planners to further promote sound land use and floodplain development. Minimum floodplain management requirements for participation in the National Flood Insurance Program (NFIP) are set forth in the Code of Federal Regulations at 44 CFR, 60.3.

In some states or communities, floodplain management criteria or regulations may exist that are more restrictive or comprehensive than the minimum Federal requirements. In such cases, the more restrictive criteria take precedence and the State (or other jurisdictional agency) will be able to explain them.

The Digital Flood Insurance Rate Map (DFIRM) and FIS report for this countywide study have been produced in digital format. Flood hazard information was converted to meet the Federal Emergency Management Agency (FEMA) DFIRM database specifications and Geographic Information System (GIS) format requirements. The flood hazard information was created and is provided in a digital format so that it can be incorporated into local GIS and be accessed more easily by the community.

Furthermore, the Towns of Cromwell and Wolcottville do not have special flood hazard areas within their incorporated limits. However, for the purpose of complete countywide mapping of Noble County, these towns are still included in this FIS and FIRMs.

1.2 Authority and Acknowledgments

The sources of authority for this Flood Insurance Study are the National Flood Insurance Act of 1968 and the Flood Disaster Protection Act of 1973.

Information of the authority and acknowledgements for each of the new studies and previously printed FIS reports and Flood Insurance Rate Maps (FIRMs) for communities within Noble County was compiled and is shown below:

Kendallville, City of: The hydrologic and hydraulic analyses for this study were performed by the U.S. Department of Agriculture, Soil Conservation Service, for the Federal Emergency Management Agency, under Inter-Agency Agreement IAA-H-11-79. Hydrologic and hydraulic analyses for flooding outside the corporate limits but within the extraterritorial limits of the City of Kendallville were taken from the Unincorporated Areas of Noble County Flood Insurance Study (Reference 1). This study was completed in June 1981.

Ligonier, City of: The hydrologic and hydraulic analyses for this study were performed by the U.S. Department of Agriculture, Soil Conservation Service, for the Federal Emergency Management Agency, under Inter-Agency Agreement IAA-H-11-79. Hydrologic and hydraulic analyses for flooding outside the corporate limits but within the extraterritorial limits of the City of Ligonier were taken from the Unincorporated Areas of Noble County Flood Insurance Study (Reference 1). This study was completed in June 1981.

Noble County
(unincorporated areas): The hydrologic and hydraulic analyses for this study were performed by the U.S. Soil Conservation Service for the Federal Emergency Management Agency, under Inter-Agency Agreement IAA-H-18-75, Project Order No. 5, supplemented by Inter-Agency Agreement No. IAA-H-8-77, Project Order No. 3. This work, which was completed in December 1976, covered all significant flooding sources in Noble County.

Rome City, Town of: The hydrologic and hydraulic analyses for this study were performed by the U.S. Department of Agriculture, Soil Conservation Service, for the Federal Emergency Management Agency, under Inter-Agency Agreement

IAA-H-11-79, Project Order No. 13. This study was completed in June 1981.

New Studies:

The hydrologic and hydraulic analyses for approximate stream reaches of Noble County were performed by Christopher B. Burke, Ltd., on behalf of the Indiana Department of Natural Resources and Maumee River Basin Commission. The Indiana Department of Natural Resources managed the production of this study as part of their Cooperating Technical Partner agreement with the Federal Emergency Management Agency dated April 29, 2004, which was defined by the Indiana DNR Mapping Activity Statement 07-17 dated July 17, 2007 and funded under agreement number EMC-2007-CA-7027.

Redelineation of the previously effective flood hazard information for this FIS report, correction to the North American Vertical Datum of 1988, and conversion of the unincorporated and incorporated areas of Noble County into the Countywide format was performed by Christopher B. Burke, Ltd., on behalf of the Indiana Department of Natural Resources and Maumee River Basin Commission, under Indiana Public Works Project Number --. The Indiana Department of Natural Resources managed the production of this study as part of their Cooperating Technical Partner agreement with the Federal Emergency Management Agency dated April 29, 2004, which was defined by the Indiana DNR Mapping Activity Statement 07-17 dated July 17, 2007 and funded under agreement number EMC-2005-GR-7022.

1.3 Coordination

The purpose of an initial Consultation Coordinated Officer's (CCOs) meeting is to discuss the scope of the FIS. A final CCO meeting is held to review the results of the study. The dates of the initial and final CCO meetings held for the previously effective FIS reports covering the geographic area of Noble County, Indiana are shown in Table 1 (References 1). The initial and final CCO meetings were attended by the study contractor, FEMA (or the Federal Insurance Administration), the Indiana Department of Natural Resources (IDNR), and the affected communities.

Table 1: CCO Meeting Dates for Pre-Countywide FIS

| <u>Community Name</u> | <u>Initial CCO Date</u> | <u>Final CCO Date</u> |
|--|-------------------------|-----------------------|
| Noble County, IN (Unincorporated Areas) | January 1975 | March 9, 1977 |
| Kendallville, City of | June 6, 1979 | January 28, 1982 |
| Ligonier, City of | N/A | December 1, 1981 |
| Rome City, Town of | June 6, 1979 | December 1, 1981 |

For this countywide FIS, an initial CCO meeting was held on August 29, 2006, and was attended by IDNR, the Noble County Plan Commission, the Noble County Surveyor, and the Town of Yorktown.

The results of the countywide study were reviewed at the final CCO meeting held on --, and attended by representatives of FEMA, IDNR and representatives from Noble County. All problems raised at that meeting have been addressed.

2.0 AREA STUDIED

2.1 Scope of Study

This FIS covers the geographic area of Noble County, Indiana, including the incorporated communities listed in Section 1.1

All FIRM panels for Noble County have been revised, updated, and republished in countywide format as a part of this FIS. The FIRM panel index, provided as Exhibit 2, illustrates the revised FIRM panel layout.

Approximate methods of analysis were used to study those areas having a low development potential or minimal flood hazards as identified during the initial CCO meeting. For this study, eleven new stream reaches were studied using approximate methods. The scope and methods of new approximate studies were proposed and agreed upon by FEMA, the IDNR, and Noble County.

This FIS update also incorporates the determination of letters issued by FEMA resulting in map changes (Letters of Map Change, or LOMCs). All Letters of Map Revision (LOMRs) are summarized in Table 2. Channel cross section and bridge data for Willow Creek were field surveyed by the Detroit District COE. Channel cross section and bridge data for Eley Drain, Van Gorder Drain, Black Creek, and Little Cedar Creek were field surveyed by Christopher B. Burke Engineering, Ltd. Letters of Map Amendment (LOMAs) for this study are summarized in the Summary of Map Actions (SOMA) included in the Technical Support Data Notebook (TSDN) associated with this FIS update. Copies of the TSDN may be obtained from the Community Map Repository.

Table 2: Incorporated Letters of Map Change

| <u>Flooding Source</u> | <u>Community and Project Id</u> | <u>Date Issued</u> | <u>Type</u> |

| Willow Creek ⁺ | CR 800 E to 2700' upstream of CR 500 S |
| Yarde Ditch ⁺ | B & O Railroad to Noble/DeKalb Co. line |

** Various Lakes include: Baugher Lake, Bear Lake, Big Lake, Bixler Lake, Chain O'Lakes, Crooked Lake, Deer Lake, Engle Lake, Henderson Lake, High Lake, Jones Lake, Knapp Lake, Little Long Lake, Lower Long Lake, Muncie Lake, Round Lake, Skinner Lake, Smalley Lake, Sylvan Lake, Upper Long Lake, Waldron Lake, and Williams Lake

⁺Additional studies funded by the Maumee River Basin Commission (MRBC) included in this revision.

2.2 Community Description

Noble County (412 square miles in area) is located in north-central Indiana and is bordered by LaGrange County to the north, DeKalb County to the east, Whitley and Allen Counties to the south, and Elkhart and Kosciusko Counties to the west. Noble County is located approximately 120 miles northeast of Indianapolis. Noble County is served by US routes 33 and 6, and State Routes 3, 5, 8, and 9. The City of Kendallville is located in northeast Noble County. The Town of Rome City is located in north-central Noble County. The City of Ligonier is located in the northwestern part of Noble County. Many lakes, mostly of natural origin, exist in the county, and are used extensively for water sports and fishing. Cabins and houses often exist near the shorelines of the lakes. Extensive wetlands are an important feature of the landscape and are valuable wildlife habitats.

The Elkhart River is the principal drainage outlet for Noble County. Formed by the confluence of the North Branch Elkhart River and the South Branch Elkhart River at a point about 3.5 miles east of Ligonier, Indiana, the Elkhart River flows northwestward to its junction with the St. Joseph River at Elkhart, Indiana. About 10 miles of this river are in Noble County with about 36 miles downstream of the county line. At the county line the Elkhart River drainage area is 303 square miles. Other

streams within the St. Joseph River sub-basin flowing from Noble County are Little Elkhart Creek, Solomon Creek, and Turkey Creek. Seventy-five percent of the Noble County lies within this sub-basin. Flow characteristics of this area are perennial by nature, due principally to substantial areas of wetlands, natural lakes, and groundwater reservoirs. Comparatively strong low flow discharges and correspondingly temperate peak discharges are experienced. The only major artificial lake is Sylvan Lake at Rome City. The natural stream system in the upper watersheds is largely comprised of channels connecting the many natural lakes. These channels are inherently shallow streams meandering through marsh lands.

The Tippecanoe River drainage area (part of the Wabash River sub-basin of the Ohio River basin) is 36 square miles, makes up approximately 10% of Noble County, and is located in the southwest corner of the county. Like the St. Joseph River sub-basin area, flow is perennial and natural lakes are a dominant landscape feature. Wilmot Pond is the only major artificial lake.

In the southeast corner of the county, Sycamore Creek, Little Cedar Creek, Black Creek, and Willow Creek all drain to the Maumee River sub-basin of the Great Lakes basin. Fifteen percent of the county lies in this sub-basin. Little Cedar Creek has headwaters in adjacent Dekalb County and after only about two miles in Noble County returns to Dekalb County. This stream has about 35 square miles of drainage area in the study area. The other three streams mentioned above originate in Noble County. There are virtually no natural lakes in this part of the county; topography is more rolling and consequently fluctuation in stream flow is more pronounced.

Bixler Lake Ditch flows westerly through south-central Kendallville and turns north at the west edge of the golf course. North of the railroad tracks, part of its waters is diverted into Henderson Lake and the rest enters Henderson Lake Ditch. The drainage area for Bixler Lake Ditch at Henderson Lake is approximately six square miles. Waterhouse Ditch flows westerly through northern Kendallville and drains into Henderson Lake Ditch west of the city.

Sylvan Lake lies within the town limits of Rome City. Many residential buildings occupy the shoreline of the lake. Henderson Lake Ditch drains into Sylvan Lake at the east edge of Rome City. Sylvan Lake discharges into Branch Creek near the west side of Rome City. Branch Creek joins the North Branch Elkhart River at Jones and Waldron Lakes.

Sparta Lake Ditch joins the Elkhart River on the east edge of Ligonier. Its drainage area is 4.7 square miles. Solomon Creek flows in a northwesterly direction within the southwestern portion of Ligonier's extraterritorial limits. Its drainage area is 16.2 square miles.

Land use in the flood plains of unincorporated Noble County is of relatively low agricultural intensity with about one-fourth in cropland. The wetlands occupy about one-third of the flood plain and are marshy or swamped areas. Grassland, forest land

and other land account for the balance. Several residences and a few businesses are located in flood-prone areas throughout the county. Concentrations of houses in flood-prone areas occur near certain lakes.

Land use in the floodplain of Henderson Lake Ditch is relatively low in agricultural intensity; Bixler Lake Ditch and Lash Ditch flood plains consists of a golf course, industrial and residential areas, a school playground, a city park, and wetlands.

The climate in Noble County ranges from hot and humid in the summertime to cold during the winter season. Average daytime temperatures during the summer fall around 69.6 °F, while winter temperatures average at approximately 24.7°F. Precipitation for Noble County totals an annual amount of 37.30 inches.

According to U.S. Census Data from the year 2000, the population of Noble County was reported to be 46,275. Table 6 lists the population of the incorporated areas in Noble County.

Table 6: Population of incorporated cities and towns in Noble County (2000 Census)

| <u>Community</u> | <u>Population</u> |
|-----------------------|-------------------|
| Albion, Town of | 2,284 |
| Avilla, Town of | 2,049 |
| Cromwell, Town of | 452 |
| Kendallville, City Of | 9,616 |
| Ligonier, City Of | 4,357 |
| Rome City, Town Of | 1,615 |
| Wolcottville, Town Of | 933 |

2.3 Principal Flood Problems

Major flooding in Noble County primarily occurs along the North Branch Elkhart River and its tributaries. Major floods principally occur during the winter and spring months, but can occur during any season. Generally, two types of storm events cause flooding. During the winter and spring, storms of moderate intensity and long duration, coupled with frozen ground, cause flooding to occur. During the summer, thunderstorms which have high intensities and relatively short durations can cause floods. Localized flood problems in the incorporated areas are summarized below:

| | |
|------------------|--|
| Albion, Town of: | The discharges and flood elevations on floods at the gaging stations on the Rimmel Ditch near Albion are as follows: |

| 1997 | 576 | 6.86 |
| 1998 | 688 | 7.61 |
| 1999 | 561 | 7.21 |
| 2005 | 519 | 6.53 |

Kendallville, City of: Forty years of records show that damaging floods have occurred in March 1939, May 1943, April 1950, July 1951, October 1954, February 1956, April 1956, December 1966 and February 1968. Of these floods, the largest were 1943 1950, 1951 and 1954 events. The magnitude of these floods ranges from 20- to 30-year recurrence intervals. Floods during the 1960 through 1976 period have been relatively small in comparison with the past and with what can be expected in the future. The discharges and flood elevations on floods at the gaging stations on the Wible Lake Inlet near Kendallville are as follows:

Table 10: Flood Crest Elevations
USGS gage for Wible Lake Inlet near Kendallville

| <u>Year</u> | <u>Discharge</u> <u>Cubic Feet Per Second (CFS)</u> | <u>Elevation</u> <u>(feet, gage datum)</u> |
|-------------|--|---|
| 1976 | 28.0 | 4.25 |
| 1977 | 35.0 | 4.51 |

2.4 Flood Protection Measures

There are no National Flood Insurance Program approved flood control structures showing protection from the mapped floodzone.

Precounty-wide studies: Stream gaging station records of the North Branch Elkhart River near Cosperville, and the Elkhart River at Goshen were the principal sources of data for defining discharge-frequency relationships for the studied streams. Discharges were statistically analyzed principally by the Log-Pearson type III distribution of annual peak flow data.

Stream channel clearance along 18 miles of the North Branch, South Branch, and main stem of Elkhart River was done in 1975. This work was accomplished through financial sponsorship by Title 10, Public Works and Economic Development Act of 1965, as amended. Debris was removed from these streams and trees growing on stream banks where potential snagging problems existed were cut and removed to allow more efficient water flow. The effects of the above work were accounted for in this Flood Insurance Study.

The Elkhart River Basin, Indiana, Report on Water and Related Land Resources, recommended 0.6 mile of channel work for flood control and increased recreation along Turkey Creek near the outlet of Knapp Lake. This report also recommended 2.2 miles of channel work on Carrol Creek west of Muncie Lake. The effects of work stemming from these two recommendations were not accounted for in performing this Flood Insurance Study as no construction has been authorized.

The Tippecanoe River in Noble County was excavated many years ago at most locations between lakes to lower the original water-surface for improved drainage of surrounding fields. Other stream channels removed from the lakes have been straightened and deepened to facilitate improved drainage of adjacent fields.

3.0 ENGINEERING METHODS

For the flooding sources studied by detailed methods in Noble County, standard hydrologic and hydraulic study methods were used to determine the flood hazard data required for this study. Flood events of a magnitude that are expected to be equaled or exceeded once on the average during any 10-, 50-, 100-, or 500-year period (recurrence interval) have been selected as having special significance for floodplain management and for flood insurance rates. These events, commonly termed the 10-, 50-, 100-, and 500-year floods, have a 10-, 2-, 1-, and 0.2-percent chance, respectively, of being equaled or exceeded during any year. Although the recurrence interval represents the long-term, average period between floods of a specific magnitude, rare floods could occur at short intervals or even within the same year. The risk of experiencing a rare flood increases when periods greater than 1 year are considered. For example, the risk of having a flood that equals or exceeds the 1-percent-annual-chance flood in any 50-year period is approximately 40 percent (4 in 10); for any 90-

year period, the risk increases to approximately 60 percent (6 in 10). The analyses reported herein reflect flooding potentials based on conditions existing in the community at the time of completion of this study. Maps and flood elevations will be amended periodically to reflect future changes.

3.1 Hydrologic Analyses

Hydrologic analyses were carried out to establish peak discharge-frequency relationships for each flooding source studied by detailed methods affecting Noble County. Table 11 contains a summary of peak discharges for the 10-, 2-, 1-, and 0.2-percent annual chance floods, where applicable, for each flooding source studied in detail in Noble County. Peak discharges for Bixler Lake Ditch and Lash Ditch were computed using GeoHMS tools in ArcGIS which was then imported into HEC-HMS. Peak discharges for all other streams in the table were compiled from previously effective FIS reports for Noble County and incorporated areas.

Standard and accepted hydrologic methods were used to develop discharge data on the study streams in Noble County. The equations used to determine the discharges in the majority of the cases are taken from Estimation of Peak Discharges of Indiana Streams by using log Pearson (iii) distribution. The equations presented in the report are also included in the latest version of the National Flood Frequency (NFF) program by the USGS, and are included in the USGS StreamStats application. In some cases, the discharges for a stream have been coordinated with the Indiana Department of Natural Resources, the Natural Resources Conservation Service (formally the Soil Conservation Service), the U.S. Geological Survey and the U.S. Army Corps of Engineers, through a Memorandum of Understanding dated May 6, 1976.

3.2 Hydraulic Analyses

Analyses of the hydraulic characteristics of flooding from the sources studied were carried out to provide estimates of the elevations of floods of the selected recurrence intervals. Users should be aware that flood elevations shown on the Flood Insurance Rate Map (FIRM) represent rounded whole-foot elevations and may not exactly reflect the elevations shown on the Flood Profiles or in the Floodway Data table in

the FIS report. Flood elevations shown on the FIRM are primarily intended for flood insurance rating purposes. For construction and/or floodplain management purposes, users are cautioned to use the flood elevation data presented in this FIS report in conjunction with the data shown on the FIRM.

Cross sections for the backwater analyses were obtained from a variety of sources including: physical survey data, IDNR contour mapping, USGS topographic mapping and local contour mapping. Photogrammetric methods were adapted to develop a two-foot contour interval topographic for the Elkhart River and its floodplain for the previous City of Ligonier study, and Henderson Lake Ditch & Waterhouse Ditch for the previous City of Kendallville study.

For the new approximate study reaches, the USACE HEC-RAS program was used. HEC-RAS is an updated version of the HEC-2 program used to perform step-backwater analyses.

Precounty-wide studies: Starting water surface elevations for a tributary of a studied stream or lake were taken from flood frequency profiles of the receiving water at the junction. Concurrent flood peaking of the tributary and receiving waters was assumed. Within the backwater area from a receiving stream, computed profiles for a tributary show very little increase in flood heights above backwater elevations. Water-surface elevations for floods of the selected recurrence intervals were computed through use of the SCS (currently NRCS) WSP-2 step-backwater computer program. Likewise, the computed profiles generally reached normal depth within a short distance upstream of backwater locations further justifying use of concurrent flood peaks at junctions. Water surface slope for normal flow was used for starting flood profiles for streams finding outlets beyond the Noble County line. From this slope the normal depth was computed at the starting cross section. The starting section was sufficiently far downstream to assure accurate profile elevations where computations reached the study area.

Little Lake elevations are based on the upstream end of the Branch Creek study. Bixler Lake elevations were based on lake gage data records. The 0.2% frequency elevation was revised based on the revised study for Lash Ditch

Table 12: Stillwater Elevations

| <u>Flooding Source</u> | <u>Static Base Flood Elevation (feet NAVD 88)</u> |
|------------------------|---|
| Baughner Lake | 882.3 |
| Bear Lake | 895.9 |
| Bixler Lake | 966.1 |
| Big Lake | 901.5 |
| Crooked Lake | 906.7 |
| Engle Lake | 879.3 |

Table 12: Stillwater Elevations (cont.)

| <u>Flooding Source</u> | <u>Static Base Flood Elevation (feet NAVD 88)</u> |
|------------------------|---|
| High Lake | 898.3 |
| Jones Lake | 890.0 |
| Knapp Lake | 880.7 |
| Little Lake | 894.1 |
| Little Long Lake | 954.3 |
| Lower Long Lake | 891.5 |
| Muncie Lake | 890.3 |
| Round Lake | 954.3 |
| Skinner Lake | 933.7 |
| Smalley Lake | 887.1 |
| Sylvan Lake | 918.8 |
| Upper Long Lake | 893.2 |
| Waldron Lake | 890.0 |
| Williams Lake | 890.1 |

For this revision: The Bixler Lake Ditch and Lash Ditch detailed studies, two-foot contours of the area and manually drawn cross-sections were manipulated in ArcGIS using HEC-GeoRAS tools. This data was then imported into HEC-RAS to compute the water surface elevations.

Sylvan Lake elevations were revised based on the hydraulic modeling for the Emergency Action Plan for Sylvan Lake Dam.

Flood profiles were prepared for all streams studied by detailed methods and show computed water-surface elevations to an accuracy of 0.5 feet for floods of the selected recurrence intervals. For this countywide FIS, flood profiles and approved LOMRs have been consolidated into continuous stream reaches and adjusted to reflect the current vertical datum as described in Section 3.3. New profiles have been prepared for the new detailed studies and for the purposes of incorporating the LOMRs described in Section 2.1 above.

Channel and overbank roughness factors (Manning’s “n” values) used in the hydraulic computations were chosen by engineering judgment and were based on field observations of the stream and floodplain areas. For Bixler Lake Ditch and Lash Ditch, n-values were estimated from field observations and aerial photographs. Channel and overbank roughness factors used in the detailed studies are summarized by stream in Table 13.

Table 13. Channel and Overbank Roughness Factors

| <u>Stream</u> | <u>Roughness Coefficients</u> | |

*0.02 Channel “n” for Lakes

For new Zone A study areas, analyses were based on field inspection and modeling of the stream reaches using simplified HEC-RAS models. Structural measurements or field surveying was not performed. Cross section geometry was derived from the 2005 statewide orthophotography project with a maximum spacing of 100 feet. Starting elevations were assumed to be normal depth.

The hydraulic analyses for this study were based on unobstructed flow. The flood elevations shown on the Flood Profiles (Exhibit 1) are thus considered valid only if hydraulic structures remain unobstructed, operate properly, and do not fail.

3.3 Vertical Datum

All FIS reports and FIRMs are referenced to a specific vertical datum. The vertical datum provides a starting point against which flood, ground, and structure elevations can be referenced and compared. Until recently, the standard vertical datum in use for newly created or revised FIS reports and FIRMs was the National Geodetic Vertical Datum of 1929 (NGVD29). With the finalization of the North American Vertical Datum of 1988 (NAVD88), many FIS reports and FIRMs are being prepared using NAVD88 as the referenced vertical datum.

All flood elevations shown in this FIS report and on the FIRM are referenced to NAVD88. Structure and ground elevations in the community must, therefore, be referenced to NAVD88. It is important to note that adjacent communities may be referenced to NGVD29. This may result in differences in Base Flood Elevations (BFEs) across the corporate limits between the communities.

In this revision, a vertical datum conversion of -0.46 feet was calculated at the centroid of the county and used to convert all elevations in Noble county from NGVD29 to NAVD88 using the National Geologic Survey's VERTCON online utility (VERTCON, 2005).

$$(\text{NGVD29} - 0.46 = \text{NAVD88})$$

For more information on NAVD88, see the FEMA publication entitled Converting the National Flood Insurance Program to the North American Vertical Datum of 1988 (FEMA, June 1992), or contact the Vertical Network Branch, National Geodetic Survey, Coast and Geodetic Survey, National Oceanic and Atmospheric Administration, Rockville, Maryland 20910 (Internet address <http://www.ngs.noaa.gov>).

Temporary vertical monuments are often established during the preparation of a flood hazard analysis for the purpose of establishing local vertical control. Although these monuments are not shown on the FIRM, they may be found in the Technical Support Data Notebook associated with the FIS report and FIRM for this community. Interested individuals may contact FEMA to access these data.

The coordinate system used for the production of the digital FIRMs is the Transverse Mercator projection, Indiana State Plane coordinate system, East Zone, referenced to the North American Datum of 1983 and the GRS 1980 spheroid.

4.0 FLOODPLAIN MANAGEMENT APPLICATIONS

The NFIP encourages State and local governments to adopt sound floodplain management programs. Therefore, each FIS provides 1-percent-annual-chance flood elevations and delineations of the 1- and 0.2-percent-annual-chance floodplain

boundaries and 1-percent-annual-chance floodway to assist communities in developing floodplain management measures. This information is presented on the FIRM and in many components of the FIS report, including Flood Profiles, and the Floodway Data table. Users should reference the data presented in the FIS report as well as additional information that may be available at the local map repository before making flood elevation and/or floodplain boundary determinations.

4.1 Floodplain Boundaries

To provide a national standard without regional discrimination, the 1-percent-annual-chance flood has been adopted by FEMA as the base flood for floodplain management purposes. The 0.2-percent-annual-chance flood is employed to indicate additional areas of flood risk in the community. For each stream studied by detailed methods, the 1- and 0.2-percent-annual-chance floodplain boundaries have been delineated using the flood elevations determined at each cross section. Between cross sections, the boundaries were interpolated using topographic mapping from the City of Muncie and from the 2005 statewide orthophotography flight.

The 1- and 0.2-percent-annual-chance floodplain boundaries are shown on the FIRM (Exhibit 2). On this map, the 1-percent-annual-chance floodplain boundary corresponds to the boundary of the areas of special flood hazards (Zones A, AE, V, and VE); and the 0.2-percent-annual-chance floodplain boundary corresponds to the boundary of areas of moderate flood hazards. In cases where the 1- and 0.2-percent-annual-chance floodplain boundaries are close together, only the 1-percent-annual-chance floodplain boundary has been shown. Small areas within the floodplain boundaries may lie above the flood elevations but cannot be shown due to limitations of the map scale and/or lack of detailed topographic data.

For the streams studied by approximate methods, only the 1-percent-annual chance floodplain boundary is shown on the FIRM (Exhibit 2).

4.2 Floodways

Encroachment on floodplains, such as structures and fill, reduces flood-carrying capacity, increases flood heights and velocities, and increases flood hazards in areas beyond the encroachment itself. One aspect of floodplain management involves balancing the economic gain from floodplain development against the resulting increase in flood hazard. For purposes of the NFIP, a floodway is used as a tool to assist local communities in this aspect of floodplain management. Under this concept, the area of the 1-percent-annual-chance floodplain is divided into a floodway and a floodway fringe. The floodway is the channel of a stream, plus any adjacent floodplain areas, that must be kept free of encroachment so that the 1-percent-annual-chance flood can be carried without substantial increases in flood heights. Minimum Federal standards limit such increases to 1.0 foot, provided that hazardous velocities are not produced. The floodways in this study are presented to local agencies as

minimum standards that can be adopted directly or that can be used as a basis for additional floodway studies.

The State of Indiana, however, per Indiana Code IC 14-28-1 and Indiana Administrative Code 312 IAC 10, has designated that encroachment in the floodplain is limited to that which will cause no significant increase in flood height. Typically, floodways for this study are delineated based on a flood surcharge of less than 0.15 feet.

However, for the precounty-wide studies complete from February 1978 to July 1982, a floodway having no more than a 0.2 foot surcharge has been delineated with the approval of the Natural Resources Commission of the IDNR. The floodways in this study were approved by the IDNR, and are presented to local agencies as minimum standards that can be adopted directly or that can be used as a basis for additional floodway studies.

The floodway presented in this FIS report and on the FIRM was computed for certain stream segments on the basis of equal conveyance reduction from each side of the floodplain. Floodway widths were computed at cross sections. Between cross sections, the floodway boundaries were interpolated. The results of the floodway computations have been tabulated for selected cross sections (Table 14). In cases where the floodway and 1-percent-annual-chance floodplain boundaries are either close together or collinear, only the floodway boundary has been shown.

A floodway designation generally is not appropriate in areas which may be inundated by flood waters over wetlands and where no channel is apparent. Thus, no floodways were prepared for selected areas along the following streams: Carrol Creek, Crane Lake Ditch, Diamond Lake Ditch, Forker Creek, Gilbert Lake Ditch, Henderson Lake Ditch, Little Elkhart Creek, Long Lake Ditch, North Branch Elkhart River, Rimmel Ditch, Solomon Creek, South Branch Elkhart River, Sparta Lake Ditch, Tippecanoe River, Turkey Creek, and Waterhouse Ditch.

The area between the floodway and 1-percent-annual-chance floodplain boundaries is termed the floodway fringe. The floodway fringe encompasses the portion of the floodplain that could be completely obstructed without increasing the water-surface elevation of the 1-percent-annual-chance flood more than 0.14 foot at any point. Typical relationships between the floodway and the floodway fringe and their significance to floodplain development are shown in Figure 2.

Figure 1: Floodway Schematic

| FLOODING SOURCE | | FLOODWAY | | | 1-PERCENT-ANNUAL-CHANCE FLOOD WATER SURFACE ELEVATION | | | |
|--------------------------|-----------------------|-----------------|-------------------------------|------------------------------|---|-------------------------------------|----------------------------------|--------------------|

5.0 INSURANCE APPLICATIONS

For flood insurance rating purposes, flood insurance zone designations are assigned to a community based on the results of the engineering analyses. These zones are as follows:

Zone A

Zone A is the flood insurance risk zone that corresponds to the 1-percent-annual-chance floodplains that are determined in the FIS by approximate methods. Because detailed hydraulic analyses are not performed for such areas, no BFEs or base flood depths are shown within this zone.

Zone AE

Zone AE is the flood insurance risk zone that corresponds to the 1-percent-annual-chance floodplains that are determined in the FIS by detailed methods. In most instances, whole-foot BFEs derived from the detailed hydraulic analyses are shown at selected intervals within this zone.

Zone X

Zone X is the flood insurance risk zone that corresponds to areas outside the 0.2-percent-annual-chance floodplain, areas within the 0.2-percent-annual-chance floodplain, and areas of 1-percent-annual-chance flooding where average depths are less than 1 foot, areas of 1-percent-annual-chance flooding where the contributing drainage area is less than 1 square mile, and areas protected from the 1-percent-annual-chance flood by levees. No BFEs or base flood depths are shown within this zone.

6.0 FLOOD INSURANCE RATE MAP

The FIRM is designed for flood insurance and floodplain management applications.

For flood insurance applications, the map designates flood insurance risk zones as described in Section 5.0 and, in the 1-percent-annual-chance floodplains that were studied by detailed methods, shows selected whole-foot BFEs or average depths. Insurance agents use the zones and BFEs in conjunction with information on structures and their contents to assign premium rates for flood insurance policies.

For floodplain management applications, the map shows by tints, screens, and symbols, the 1- and 0.2-percent-annual-chance floodplains, floodways, and the locations of selected cross sections used in the hydraulic analyses and floodway computations.

The current FIRM presents flooding information for the entire geographic area of Noble County. Previously, separate FIRMs were prepared for each identified flood prone incorporated community and for the unincorporated areas of the county. Historical data relating to the maps prepared for each community are presented in Table 15.

7.0 OTHER STUDIES

This FIS report either supersedes or is compatible with all previous studies on streams studied in this report and should be considered authoritative for purposes of the NFIP.

8.0 LOCATION OF DATA

Information concerning the pertinent data used in the preparation of this study can be obtained by contacting the Flood Insurance and Mitigation Division, Federal Emergency Management Agency, Region V, 536 S. Clark Street, 6th Floor, Chicago, IL 60605.
